# Silent Speech

## Sub-audible speech recognition based on electromyographic signals

Human-to-human or human to machine communication occurs in many ways. Traditionally, visual and verbal processes dominate both the method and the presentation formats. As a result, technology to enhance human communication has focused on public, audible tasks such as those addressed by commercial speech recognition.

An alternative way of communicating developed at NASA Ames Research Center is based on the direct interpretation of nervous system control signals sent to speech muscles by the brain. We interpret non invasive aggregate surface measurements of ElectroMyographic Signals (EMGs) to categorize muscle activations prior to sound generation. Such signals arise when reading or speaking to oneself with or without actual lip or facial movements. Hence obtaining the speech information does not require visual observation, such as machine lip reading, to enhance recognition in high noise. The general use of EMG signals has permitted us to demonstrate several new ways to perform common interface functions including joystick control, keyboard typing, and simple speech command interfacing.

## BENEFITS

- Minimal of word variations
- Shared language and shared sound production
- Reliability
- Reasonably accuracy
- Resistance to presence of noise
- Soundless communication in difficult environments
- Mimic of an idealized thought-based approach
- Non-invasive sensing
- Privacy

technology solution

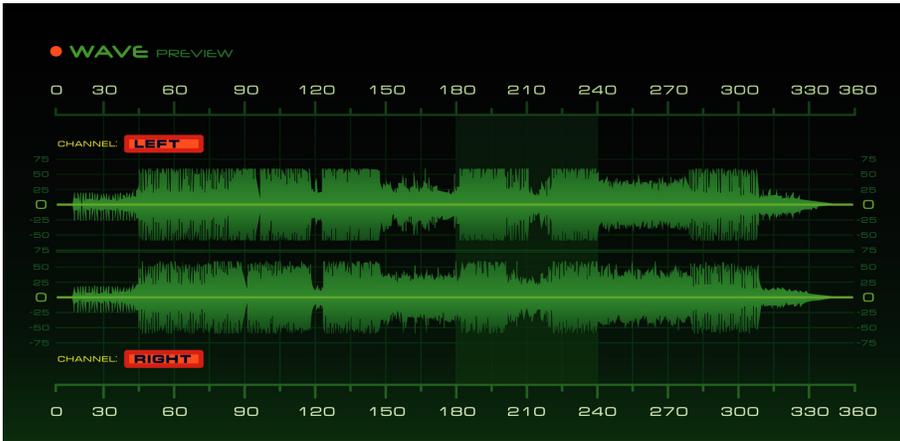

# NASA Technology Transfer Program

Bringing NASA Technology Down to Earth

## THE TECHNOLOGY

Silent speech seeks to increase the options available to future habitat designers by creating the technical infrastructure for transportable, multi-equipment, human machine interfaces. Freeing future hardware designs of many of the constraints of human physical instrumentality will save payload weight, increase design robustness, and standardize interface training requirements of exploration system missions.

Our research is concerned with developing the full potential of electromyographic signal (EMG) interfaces to enhance NASA human exploration missions. We are approaching this goal through a series of increasingly sophisticated experiments, implementation prototypes, and wearable non-intrusive sensor developments. One of these sets of experiments deals with sub-vocal speech recognition. In this work, we are using surface signals from the larynx and sub-lingual areas of the neck and throat to recognize silently mouthed control words and to identify speakers biometrically based on living neural signal characteristics. Current implementations use EMG interfaces to control a simulated Mars rover in real-time and to perform a typical information gathering/web browsing task. We plan on extending the present simple speech recognition capabilities by extracting increasingly fine detail from EMG signals to determine their underlying vowel and consonant structure, move toward real-time continuous speech recognition, and explore an alternative method, direct speech coding, taken from the EMG signal to enable true human-to-human noise immune communication. We will also be extending simulated control to real control of a robotic vehicle and testing the performance of the method with alternative atmospheric breathing gas mixtures closer to space conditions.

## APPLICATIONS

The technology has several potential applications:

- Human-to-machine commands
- Military operations
- Physical and speech-disabled persons
- Underwater operations
- Medical and emergency service workers
- Homeland security
- Interactive database searches
- Robotic command/control

NASA's Technology Transfer Program pursues the widest possible applications of agency technology to benefit US citizens. Through partnerships and licensing agreements with industry, the program ensures that NASA's investments in pioneering research find secondary uses that benefit the economy, create jobs, and improve quality of life.
